```
    [2] => Rita
    [3] => Sue
    [4] => Russell
)
```

`array_merge()` does exactly what it says and merges two arrays together and returns the result. If indexed arrays are input, then all of the values of both arrays are combined in the order they were supplied. The resulting array is then reindexed (in this case, element `0` of `$myArr2` becomes element `2` of the new array, and so on).

A word of warning: `array_merge()` behaves differently with associative arrays. If the same keys exist in the input arrays, then they will overwrite each other. Only one value will be present in the output (which will be set to whatever `array_merge()` encountered last).

```
$assoc1 = [
    'a' => 'Alice',
    'b' => 'Rita',
];

$assoc2 = [
    'a' => 'Sue',
    'b' => 'Bob',
];

print_r(array_merge($assoc1, $assoc2));

Output:
Array
(
    [a] => Sue
    [b] => Bob
)
```

Splicing into Other Arrays

If we need to insert the elements of one into an arbitrary position of another, `array_splice` is our friend (again). The method is similar to that seen earlier on in the section on array manipulation, but instead of a scalar value, we pass an array.
