```
$myArr1 = ["Alice", "Bob", "Russell"];
$myArr2 = ["Rita", "Sue"];

array_splice($myArr1, 1, 0, $myArr2); // offset = 2, length = 0
print_r($myArr1);

Output:
Array
(
    [0] => Alice
    [1] => Rita
    [2] => Sue
    [3] => Bob
    [4] => Russell
)
```

We've already seen `array_splice` in action but this time we pass another array to insert, rather than a scalar. `array_splice` will extract the elements of the array to be inserted and drop those into `$myArr1` (starting here at offset `1`) in the order they exist in `$myArr2`.

`array_splice()` can also replace elements when it splices in the new data, controlled by the second (offset) and third (length) function parameters. It is possible to replace all elements after the offset by passing `null` as the length:

```
$myArr1 = ["Alice", "Bob", "Russell"];
$myArr2 = ["Rita", "Sue"];

array_splice($myArr1, 2, null, $myArr2); // offset = 2, length = null
print_r($myArr1);

Output:
Array
(
    [0] => Alice
    [1] => Bob
    [2] => Rita
    [3] => Sue
)
```
