```
$car1 = ['make' => 'VW', 'model' => 'Golf'];
$car2 = ['make' => 'VW'];

print_r(array_intersect_key($car1, $car2));
print_r(array_diff_key($car1, $car2));

Output:
Array
(
    [make] => VW
)
Array
(
    [model] => Golf
)
```

Much like `array_intersect()`, `array_intersect_key()` compares the first input array to the second (and any subsequent) array and returns common elements. However, this time it is the keys that are compared. `$car1` and `$car2` both have the common key `make`, but it is the corresponding element of `$car1` that is placed in the returned array. `array_diff_key()` does the inverse, so it returns `model` and its value.

Comparing Keys and Values

If you wish to compare associative arrays based on keys *and* values, PHP offers the functions `array_diff_assoc()`, and `array_intersect_assoc()`. These three functions perform exactly as their non-associative counterparts, with the added condition that keys are also compared. Here are some examples:

```
$car1 = [
    'make' => 'VW',
    'model' => 'Golf',
    'variant' => 'GTI 8v',
    'colour' => 'Oak Green', // car nerds: there was a limited run of 8v
                             GTIs in this colour ;)
];
```
