```
$car2 = [
    'make' => 'VW',
    'model' => 'Golf',
    'variant' => 'GTI 16v',
    'COLOUR' => 'Oak Green',
];

print_r(array_diff_assoc($car1, $car2));
print_r(array_intersect_assoc($car1, $car2));

Output:
Array
(
    [variant] => GTI 8v
    [colour] => Oak Green
)
Array
(
    [make] => VW
    [model] => Golf
)
```

Hopefully the output makes sense given what you now know about `array_diff()` and `array_intersect()`. Note that one of the elements in the output of `array_diff()` was `[colour] => Oak Green` despite both cars being painted in this rather glorious shade. This happens because array keys are case sensitive. Fortunately, there are ways to normalize array keys before comparison.

Normalizing Keys

Should you find yourself with the task of comparing associative arrays with keys that differ in case but are otherwise equivalent (e.g., comparing `colour` to `COLOUR`) then `array_change_key_case()` is the solution. This function accepts an array as its first argument, then an optional flag (`CASE_UPPER` or `CASE_LOWER`), and returns an array with keys updated accordingly.
