```
// ... $car1 as before

$car2 = array_change_key_case($car2, CASE_LOWER);

print_r($car2);
print_r(array_diff_assoc($car1, $car2));

Output:
Array
(
    [make] => VW
    [model] => Golf
    [variant] => GTI 16v
    [colour] => Oak Green
)
Array
(
    [variant] => GTI 8v
)
```

With the two arrays now agreeing on the key for color, we get a single key and element returned from `array_diff_assoc()`. If normalizing keys requires more than just changing case, there are also functions available in PHP to compare keys and/or values using callback functions.

Comparing with Callbacks

It might sometimes be the case that comparing array elements requires a little more work than just type coercion and direct value comparison. The logic for testing equality can be more complex when the elements being compared are not scalars. The array functions we've seen in this section (`array_diff()` and `array_intersect()`) have counterparts designed to handle callback functions. (A callback occurs when function `A()` is given function `B()` as an argument – `A(B);` – with the intention that `A()` will be responsible for calling `B()` in some way, see Chapter 3, "Functions," for a deeper explanation.)

These are all the array comparison functions that accept callbacks; most accept a single callback, but there are two exceptions:
