The default behavior of `sort()` is to modify the input array rearranging its elements according to the standard rules, then re-index them. Re-indexing is fine when you need it and overly aggressive when you don't. For example, if we sort an associative array:

```
$assoc = [
    'make' => 'VW',
    'model' => 'Golf',
];

sort($assoc);
print_r($assoc);

Output:
Array
(
    [0] => Golf
    [1] => VW
)
```

… we can see that the keys have been replaced by numeric indexes. There is a sorting function designed to handle associative arrays, which we will come to shortly.

By Key

If sorting by key order is needed, then `ksort()` (to sort in ascending order, or `krsort()` for descending) will rearrange an array into key order.

```
$arr = [
    'a' => 'Alice',
    'r' => 'Russell',
    'b' => 'Bob',
];

ksort($arr);
print_r($arr);
```
