Functional Array Processing

We've seen a lot of very useful built-in functionality for common array handling tasks so far but there will inevitably be times when you will have to roll-your-own. In this section we'll look at the tools PHP gives you for more complex processing requirements.

Transforming with `array_walk()`

Sometimes it is necessary to rewrite data structures. Perhaps your program fetches data from an API call, but the data isn't well formatted for your needs. PHP provides the built-in function `array_walk()`, which allows you to apply a callback function to every element in an array:

```
$cars = [
    [
        ['make', 'VW'], ['model', 'Golf GTI']
    ],
    [
        ['make', 'VW'], ['model', 'Corrado VR6']
    ],
];

array_walk($cars, 'applySanity');
print_r($cars);

function applySanity (&$val)
{
    $val = [
        $val[0][0] => $val[0][1],
        $val[1][0] => $val[1][1],
    ];
}

Output:
Array
(
    [0] => Array
```
