```
Output:
object(stdClass)#2 (1) {
  ["hates"]=>
  string(10) "The Eagles"
}
```

As you can see, the cloned object has received the original's `hates` property. All of the cloned objects' properties will be copied, but be aware that these are "shallow" copies. Any references to other objects will remain as references on the clone:

```
$obj = new stdClass();
$obj->childObj = new stdClass();
$obj->childObj->prop = 'Original property';

$cloned = clone $obj;
$obj->childObj->prop = 'New property';

var_dump($cloned->childObj);

Output:
object(stdClass)#2 (1) {
  ["prop"]=>
  string(12) "New property"
}
```

The examples above show the fundamentals of creating objects, but the `stdClass` object we've used so far is lacking in features, and our attempts to add functionality were met with mixed success. What we really need if we're going to build a useful object in PHP is our own class.

Classes

As stated earlier, a class is a blueprint for an object. It contains a set of methods, properties, and usually some initial state for the object when it is first instantiated.
