Anonymous Classes

Since PHP 7, it has been possible to use *anonymous classes*. Like anonymous functions, these are runtime declarations that are immediately evaluated when PHP encounters them. And like anonymous functions (that evaluate to a `Closure` instance, which is then either passed to other code or assigned to a variable), anonymous classes are evaluated to an object with all the members defined in the class body, which is then either assigned to a variable or passed to other code for immediate use:

```
$bot = new class(['some', 'quotes'])
{
    public function __construct(private array $quoteStash)
    {
    }
};

var_dump($bot);

Output:
object(class@anonymous)#2 (1) {
  ["quoteStash":"class@anonymous":private]=>
  array(2) {
    [0]=>
    string(4) "some"
    [1]=>
    string(6) "quotes"
  }
}
```

An anonymous class is intended to be used when a one-off object instance is required and are usually quite simple in their construction. Here we're making use of the anonymous class constructor so we have to add parentheses after the keyword `class` (so that data can be passed into the `__construct()` method). If the constructor is not used, the statement could be simplified to `$bot = new class { ... };`. Note that a closing semicolon is necessary because this is a runtime statement.
