```
    public function setNonConstructedProp(string $val): void
    {
        $this->nonConstructedProp = $val;
    }
}

$obj = new DataObj('prop1');
var_dump($obj);
$obj->setNonConstructedProp('prop3');
$obj->setNonConstructedProp('prop4');

Output:
object(DataObj)#3 (1) {
  ["nonConstructedProp"]=>
  uninitialized(string)
  ["someProp"]=>
  string(5) "prop1"
}
Fatal error: Uncaught Error: Cannot modify readonly property
DataObj::$nonConstructedProp in ...
```

This simple data wrapper class (which is a typical use case for `readonly`) uses `readonly` both in a promoted constructor property and a regular class property. Notice we've used a setter for `$nonConstructedProp` and called the setter twice, triggering an error.

The following shows an entire `readonly` class:

```
readonly class DataObj
{
    public function __construct(
        public string $prop
    ) {
    }

    public function setProp(string $val): void
    {
        $this->prop = $val;
    }
}
```
