```
$obj = new DataObj('prop1');
$obj->setProp('new val');
```

```
Output:
Fatal error: Uncaught Error: Cannot modify readonly property
DataObj::$prop in ...
```

The error has been triggered again to demonstrate the `DataObj::$prop` has been made `readonly` via the class declaration. Both of these examples should serve to demonstrate that readonly properties are best set via a constructor (which is only ever called once).

Final Classes

It is sometimes desirable to prevent inheritance mechanisms. For this reason, we have the `final` keyword. Classes declared as `final` cannot be extended. Class constants and methods may also be declared as `final`, which prevents overloading in a subclass. The following examples demonstrate these restrictions.

Attempt to override a `final` class method:

```
class SuperClass
{
    final public function doThing(): void
    {
    }
}

class SubClass extends SuperClass
{
    public function doThing(): void
    {
    }
}
```

```
Output:
Fatal error: Cannot override final method SuperClass::doThing()
```
