```
    public static function getQuote(): string
    {
        return self::QUOTE;
    }
}
class GenericQuoteBot
{
    use GetQuote;
}

print GenericQuoteBot::getQuote() . PHP_EOL;

Output:
I am not a number! I am a free man!
```

Here we've chained our traits together: `GetQuote` defines a public static `getQuote()` method and also has a `use DefaultQuote;` statement. This means that the (now private) const in `DefaultQuote` is available in `GetQuote`. `GenericQuoteBot` uses the `GetQuote` trait, which in turn uses the `DefaultQuote` trait. The composed class declaration that is subsequently interpreted by PHP is essentially this:

```
class GenericQuoteBot
{
    //DefaultQuote trait expands to this:
    private const QUOTE = 'I am not a number! I am a free man!';

    // GetQuote trait expands to this:
    public static function getQuote(): string
    {
        return self::QUOTE;
    }

    use GetQuote;
}
```
