Let's see them in action:

```
class Magician
{
    public function debug(): void
    {
        print __CLASS__ . PHP_EOL;
        print __METHOD__ . PHP_EOL;
    }
}

$magician = new Magician();
$magician->debug();

Output:
Magician
Magician::debug
```

The code above demonstrates __CLASS__ and __METHOD__ constants. Their values correspond to the declaration they are used in, not where they are used. For example:

```
class Quentin extends Magician
{
}

$magician = new Quentin();
$magician->debug();

Output:
Magician
Magician::debug
```

The values for __METHOD__ and __CLASS__ have not changed despite being called from an instance of a child class. Likewise, __NAMESPACE__ behaves in the same way:

```
namespace Brakebills {
    class Magician
    {
        public function debug(): void
```
