```
Output:
string(8) "Magician"
string(8) "Magician"
string(7) "Quentin"
string(7) "Quentin"
```

To complement `get_class()`, `get_called_class()`, and `is_a()` all functions that are concerned with an object's class, there are also functions concerned with class hierarchy. These are `get_parent_class` and `is_subclass_of()`:

```
class Magician
{
}

class Alice extends Magician
{
}

class Niffin extends Alice
{
}

var_dump(get_parent_class(Niffin::class));
var_dump(get_parent_class(new Alice()));
var_dump(is_subclass_of(Niffin::class, Magician::class));
var_dump(is_subclass_of(new Alice, Magician::class));

Output:
string(5) "Alice"
string(8) "Magician"
bool(true)
bool(true)
```

`get_parent_class()` and `is_subclass_of()` both accept either objects or class name strings as the first argument, the second argument to `is_subclass_of()` must always be a class name string. Note that `get_parent_class()` returns the immediate parent class: `Niffin` is a subclass of `Magician` in the hierarchy, but `get_parent_class()` reports `Alice` because `Niffin` extends `Alice`.
