What Does It Do?

Finally, there are functions for finding out about class and object members. `get_class_methods()` returns public methods, `get_class_vars()` returns public properties, they both accept either object instances or class names:

```
class Wizard
{
    public int $level = 1;
    private int $exp = 0;

    public function magicMissile(): void
    {
        // hurt stuff
    }

    protected function longRest(): void
    {
        // snooze
    }
}

$wiz = new Wizard();

print_r(get_class_methods($wiz));
print_r(get_object_vars($wiz));

print_r(get_class_methods(Wizard::class));
print_r(get_class_vars(Wizard::class));
```

The output of `get_class_methods()` and `get_object_vars()` is identical for `$wiz` and `Wizard::class`:

```
Output:
Array
(
    [0] => magicMissile
)
```
