```
#[Fighter]
#[Healer]
class Monk
{
}
```

Note that the `Monk` class has both attributes; it's possible (and very common) for multiple attributes to mark a statement. With all that done, we can now introspect `Cleric|Fighter|Monk` objects during the course of execution to access the metadata. What do we do with fighters and healers? Form a party, of course:

```
class Party
{
    private array $healers = [];
    private array $fighters = [];

    public function addMember(Cleric|Barbarian|Monk $member)
    {
        $refObject = new ReflectionObject($member);
        $refAttrs = $refObject->getAttributes();
        foreach ($refAttrs as $attr) {
            if ($attr->getName() === Healer::class) {
                $this->healers[] = $member;
            }
            if ($attr->getName() === Fighter::class) {
                $this->fighters[] = $member;
            }
        }
    }

    public function getHealers(): array
    {
        return $this->healers;
    }
```
