PHP on Docker

There is a range of official PHP Docker images available at https://hub.docker.com/_/php, let's get one up and running. We'll use the `php:8.4-cli` image, which you can see has two parts compared to `hello-world`. The `php:8.4-cli` name is a combination of image and tag: `php` is the image, `8.4-cli` is the tag.

```
$ docker run php:8.4-cli
Interactive shell

php > $
```

That looked quite promising: we clearly had a PHP CLI binary running, albeit very briefly before exiting and returning us to our command prompt. Let's have a quick peek at the image metadata:

```
$ docker image inspect php:8.4-cli
...
        "Config": {
            "Hostname": "",
            "Domainname": "",
            "User": "",
            "AttachStdin": false,
            "AttachStdout": false,
            "AttachStderr": false,
            "Tty": false,
            ...
            "Cmd": [
                "php",
                "-a"
            ],
```

The default command for this image is `php -a` which puts PHP into interactive mode (we'll be looking at that in the next section) but we can also see that the Linux devices for handling input and output for command shells (`stdin` et al.) are not attached. To run a Docker container interactively, you can add a `-it` switch to the command.
