```

Multiple Versions

You can probably see that running arbitrary versions of containers is going to be a pretty straightforward affair; all you need is the correct version string and access to the image. No need to worry about managing dependencies because everything the container needs is packaged into the image already. Here's a quick demo:

```
$ docker run --rm php:7.4-cli php -v
PHP 7.4.33 (cli) (built: Nov 15 2022 06:01:17) ( NTS )
Copyright (c) The PHP Group
Zend Engine v3.4.0, Copyright (c) Zend Technologie

$ docker run --rm php:8.4-cli php -v
PHP 8.4.6 (cli) (built: Apr 11 2025 17:00:54) (NTS)
Copyright (c) The PHP Group
Built by https://github.com/docker-library/php
Zend Engine v4.4.6, Copyright (c) Zend Technologies
```

Docker makes managing multi-version environments a breeze. All of the code examples in this book were created using Docker, except where indicated. The official PHP images are lacking a couple of extensions that are required for some examples, so I have provided some image building resources at https://github.com/paultregoing/ExploringPHP8 (see the repo README.md for build instructions).

Web Server Integration

The core focus of this book is to explore PHP as a general purpose programming language, and is largely agnostic of which *Server API* (SAPI) you choose to run any of the code in (PHP Server APIs are coming up towards the end of this chapter). That said,
