```
Output:
Teス
Tス
```

As always, test your code!

Whole String

Our final set of formatting and transformation functions act on the entire input and return a string that is at least the same size. They are:

Table 8-19. *Whole string transform functions*

`str_shuffle()`	Reorder bytes randomly (not for cryptography!)
`str_repeat()`	Generate a new string that is the original string repeated N times
`strrev()`	Reverse the byte order of a string

str_shuffle()

This function simply randomly reorders all the bytes of the input string, pure and simple.

```
print str_shuffle("\xOOrandomise me");
```

```
Output:
deiem mrsona
```

The output will of course vary every time, but the function is byte-safe, and the output will always be the same length as the input. The function is definitely *not* multi-byte safe and will completely destroy such strings. Useful for inducing confusion, but the function is not intended for cryptography. We'll see better functions for those tasks shortly.

str_repeat()

Another simple function, it will simply output the input string, repeated a specified number of times:
