```
function dumpMatches(array $arr): void {
    foreach ($arr[0] as $match) {
        print bin2hex($match) . PHP_EOL;
    }
    print PHP_EOL;
}

preg_match_all('/\w\b/', $text, $matches);
dumpMatches($matches);

Output:
49
64
61
6e
74
```

The function `dumpMatches()` is a simple loop that prints the hexadecimal byte values of each matched sub-string, and we can see that the pattern `/\w\b/` matches just the word bytes without capturing the word boundary bytes. The pattern `/\w /` will perform a very similar search (the only word boundary character in `$text` is ASCII space *0x20*) but gives slightly different results:

```
preg_match_all('/\w /', $text, $matches);
dumpMatches($matches);

Output:
4920
6420
6120
6e20
7420
```

This time the word boundary character is included in the match, because the literal space in the pattern is not a zero-width assertion.
