```
        (
            [0] => green apples
        )

    [1] => Array
        (
            [0] => green
        )

)
```

Hopefully this should make sense: by localizing the alternates, we are able to match any part of the sample `$text`, which is a color followed by `'apples'`. This pattern would match `'brown apples'` or (should they exist) `'orange apples'`. The sub-pattern is in "capture mode," so the `$matches` array now has two elements: first the section(s) of the sample that match the entire expression, and a new section that contains just the section(s) matching the sub-pattern. If we add another sub-pattern, the `$matches` array will contain three sub-arrays:

```
preg_match_all('/(brown|green) (bread|apples)/', $text, $matches);
print_r($matches);
```

```
Output:
Array
(
    [0] => Array
        (
            [0] => brown bread
            [1] => green apples
        )

    [1] => Array
        (
            [0] => brown
            [1] => green
        )
```
