The difference between the two sub-patterns (`?i:brown|green`) and ((`?i`) `bread|apples`) should be apparent in the output: both are case insensitive (in an otherwise case-sensitive pattern, because there is no `i` modifier after the closing delimiter), but only the second sub-pattern will capture. It is also possible to give symbolic names to sub-patterns, which will work alongside the automatic numeric indexing. The syntax has three forms: (`?P<name>`), (`?<name>`), and (`?'name'`). The `$matches` array will now have array keys corresponding to the names chosen:

```
$text = 'brown bread, green apples, orange er... oranges';
preg_match_all("/(?'colour'brown|green) (?<type>bread|apples)/", $text,
$matches);
print_r($matches);
```

```
Output:
Array
(
    [0] => Array ...
    [colour] => Array
        (
            [0] => brown
            [1] => green
        )
    [1] => Array ...
    [type] => Array
        (
            [0] => bread
            [1] => apples
        )
    ...
```

The output has been truncated somewhat to only show the interesting parts (the array keys matching the symbolic names in the sub-patterns).
