Open up a new shell, make sure the working directory is the same as the shell running the `php:8.2-apache` container from above, and create the following `index.php` file:

```
<!DOCTYPE html>
<html>
<head>
    <title>Old school PHP</title>
</head>
<body>
    <p>This paragraph is vanilla HTML</p>
    <?php
        print "<p>This paragraph was created with PHP SAPI: <pre>" . PHP_
        SAPI . "</pre></p>";
    ?>
</body>
</html>
```

We must give the file a `.php` extension even though it is actually HTML with embedded PHP; otherwise, the Apache server (as configured in the official image) will not send it to the PHP engine for processing. Finally, open up a web browser and send it to the following location: http://localhost:8080/index.php. You should get the following page:

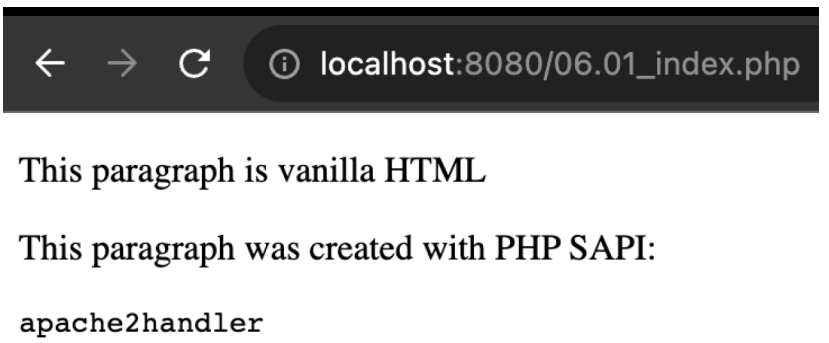

Figure 1-2. *Embedded PHP*
