Table 9-2. *DateTimeInterface methods*

`diff($dateTime, $abs)`	Returns a `DateInterval` instance based on the input `DateTimeInterface` object; `$abs` controls the behavior of the returned `DateInterval`
`format($str)`	Outputs a formatted date/time string for display, DB storage, and so on.
`getOffset()`	Returns UTC offset based on the current time zone
`getTimestamp()`	Return the Unix timestamp
`getTimezone()`	Returns the current time zone set for the object
`__wakeup()`	A "magic" method for handling serialization: see **Programming with Objects**

DateTime, DateTimeImmutable

The two core classes that see the most use in PHP tend to be `DateTime` and `DateTimeImmutable`. Both have the same interface as noted above and differ only in one respect: `DateTime` can have its value changed, but `DateTimeImmutable` cannot. The following code illustrates this point:

```
$dt = new DateTime();
var_dump($dt->getTimestamp());
$dt->modify('+1 day');
var_dump($dt->getTimestamp());

$dti = new DateTimeImmutable();
var_dump($dti->getTimestamp());
$dti->modify('+1 day');
var_dump($dti->getTimestamp());

Output:
int(1731947784)
int(1732034184)
int(1731947784)
int(1731947784)
```
