Here are some time formatting strings:

```
$dt = new DateTime('3rd September 2024 18:11:17');
// hour
print $dt->format('H h g hA ga') . PHP_EOL;
// minutes and seconds
print $dt->format('i s') . PHP_EOL;
//timezone and UTC offset - will vary with system settings if not
explicitly
//specified at construction.
print $dt->format('T O');
```

```
Output:
18 06 6 06PM 6pm
11 17
UTC +0000
```

Characters in the formatting string that don't have any special meaning will simply be rendered as-is; it's common to use punctuation such as colons, dashes, or commas:

```
print $dt->format('l, F jS, Y') . PHP_EOL;
print $dt->format('i:s i,s');
```

```
Output:
Tuesday, September 3rd, 2024
11:17 11,17
```

There are also a number of predefined global `date` constants providing some standardized formatting strings, which are also exposed by the `DateTimeInterface`. I recommend using them at least to make your code easier to understand and maintain. A few examples are given below:
