Full documentation for the functional API can be found at https://www.php.net/manual/en/ref.datetime.php, and most of the OOP methods above were covered in the previous section, so I won't go into exhaustive detail here. We will, however, be looking at the `date` module functions that don't have OOP equivalents, which are:

Table 9-8. *`date` extension function (non-OOP wrappers)*

`checkdate()`	Validates a month/day/year combination (Gregorian)
`date_default_timezone_get()`	Gets the current default TZ
`date_default_timezone_set()`	Sets the current default TZ
`date_parse()`	Return array of information from formatted string input
`date_parse_from_format()`	Same as `date_format()` but takes a second string specifying format
`date_sun_info()`	Takes a Unix timestamp, latitude, and longitude, returns sunset/sunrise/twilight information
`getdate()`	Returns array of date information from input timestamp, or current system timestamp
`gettimeofday()`	Wraps the `gettimeofday` system call, returns an array
`gmmktime()`	Returns Unix timestamp for a set of integers interpreted as a GMT date
`idate()`	Like `date()` but the format string is single character
`localtime()`	Wraps the `localtime` system call, returns an array
`microtime()`	Return current timestamp with microsecond precision
`mktime()`	Like `gmmktime()` but uses default timezone
`strtotime()`	Parses input string, returns Unix timestamp

Without further ado, let's dive in.

checkdate()

This simple function takes exactly three integer arguments representing month, day, and year (following the US convention of month before day), returning `true` if the (Gregorian) date is valid, otherwise `false`:

```
var_dump(checkdate(1, 29, 2021));
var_dump(checkdate(
```
