```
Array
(
    [year] => 2024
    [month] => 9
    [day] => 1
    [hour] =>
    [minute] =>
    ...
```

As we can see from the output, if there was no information in the input about time, there is no default (unlike a new `DateTime` object that would default to `00:00:00`). Next, we'll use `date_parse_from_format()` and include some more data:

```
print_r(date_parse_from_format(
    'Y-m-d H:i:s T',
    '2024-09-01 01:02:03 PDT'
));
```

```
Output:
    [year] => 2024
    [month] => 9
    [day] => 1
    [hour] => 1
    [minute] => 2
    [second] => 3
    ...
    [zone_type] => 2
    [zone] => -28800
    [is_dst] => 1
    [tz_abbr] => PDT
    ...
```

This time we have hours, minutes, and seconds; we also get some information about the time zone, such as its abbreviation (`PDT`) and *28800* seconds (*8* hours) behind GMT. Notice the `is_dst` element: we'll be covering things like daylight savings and leap years in the next section of the chapter. Finally, let's make a deliberate mistake:
