```
    public function getMaxPassengers()

Output:
Fatal error: Cannot override final method Vehicle::getMaxPassengers()
```

It's a bit of a brute-force technique for ensuring child classes adhere to the LSP and naturally introduces other issues: we risk violating OCP because the parent class has now become less open for extension.

Interface Segregation Principle (ISP)

This is another principle from the mind of Robert C. Martin, first published in 1996. The ISP advocates that interfaces should not be any larger than needed: that is to say that no client or subclass should be forced to depend on members it does not make use of or implement. Martin discussed "fat interfaces" and warned of classes that service the needs of different sets of clients, and such classes should be "broken up into groups of member functions."

I've mentioned design patterns already, and we'll get around to those in due course. There also exist "anti-patterns" that is patterns in OOD that are considered bad practice, and one of the worst offenders is "the blob." A blob is typically where the bulk of the system process lives, and dependent classes are usually small, contain little or no logic, and only exist to hold data. Clients of the blob are faced with a huge interface containing several (or several dozen!) methods that are of zero interest to them; subclasses of a blob now hold dozens of members that are of zero relevance to them. The source code for blob classes usually runs into thousands of lines.

Interface segregation eschews general-purpose interfaces for client-specific interfaces. Let's revisit our book empire for some examples. `Shop` and `Warehouse` both need to have orders fulfilled. Shops deal with customer orders (handling customer details in the process), and warehouses deal with wholesale orders (which require purchase orders). A component is created in our system to deal with order fulfillment and provides `wholesaleOrder()` and `customerOrder()` members in its interface. We can model the dependency between `Warehouse`, `Shop`, and `OrderFulfillment` like this:
