Note that the `http-equiv` and `name` attributes also require an additional `content` attribute. At a bare minimum, you should be using `<meta>` to tell the browser you are using UTF-8 encoding (and of course you've read Chapter 8, "Strings", and know how and why to use UTF-8 everywhere). A lot of HTML5 validators will tell you off for not declaring encoding in the document, so make sure to always include it. Some commonly used examples are given below:

```
<!DOCTYPE html>
<html>
  <head>
    <!-- tell a new browser we're in UTF-8 -->
    <meta charset="utf-8" />
    <!-- tell an older browser the same -->
    <meta http-equiv="Content-Type" content="text/html; charset=utf-8" />
    <meta name="description" content="SEO optimised stuff goes here" />
    <meta name="keywords" content="HTML, programming, PHP" />
    <title>My page.</title>
  </head>
  <body></body>
</html>
```

You can even use `<meta>` to perform a redirect (where, perhaps, the more conventional HTTP 302 / `Location:` header mechanism won't work for you), which `<meta http-equiv="refresh" content="2;url=https://www.yahoo.com" />` will force the browser to redirect to `http://www.yahoo.com` after two seconds.

Full information about the HTML `head` element can be found at `https://developer.mozilla.org/en-US/docs/Web/HTML/Reference/Elements/head`

HTML Body Content

Per the HTML5 specification, the `body` element represents the (user-facing) contents of the document. Valid HTML contains only one `body` element as an immediate child of the root `html` document element. In here you will find everything intended to be consumed by the user making the request. At this point, I could probably write another book's worth of material, but really you are (hopefully) here for the PHP side of things. That said, we'll take a look at some useful basics and go from there.
