```
Output:
string(74) "
    <meta charset="utf-8">
    <title>Block level element demo</title>
  "

// ... $validHtml and $dom as before
var_dump($dom->body->innerHTML);
```

```
Output:
string(202) "
    <main>
      <h1>Top-level heading</h1>
      <p>A simple demo of block level elements</p>
      <div>
        &lt;hgroup&gt; elements were deprecated in the HTML5 spec
      </div>
    </main>
```

The body and head properties are instances of `Dom\HTMLElement`, which are PHP class representations of HTML elements. They possess properties to represent tag names, attributes, and the special case attributes of `class` and `id`, which we'll look at in a moment.

Elements and Nodes

The DOM data structure is essentially a tree of *nodes*; all elements are nodes (`Dom\Node` instances) in addition to being types of data (such as `Dom\HTMLElement`, which is a subclass of `Dom\Node`), and this tree can be naturally navigated programmatically. `$dom->body` is an instance of `Dom\HMTLElement`, which has a `childNodes` property…

```
// ... $validHtml and $dom as before
var_dump($dom->body->childNodes);
```

```
Output:
object(Dom\NodeList)#3 (1) {
  ["length"]=>
  int(3)
}
```
