... which is a `Dom\NodeList` object. Node lists function like arrays (they are iterable and countable), so let's iterate over them:

```
// ... $validHtml and $dom as before
foreach ($dom->body->childNodes as $child) {
    print "child is an instance of " . get_class($child) . PHP_EOL;
    var_dump($child->nodeType);
}
```

```
Output:
child is an instance of Dom\Text
int(3)
child is an instance of Dom\HTMLElement
int(1)
child is an instance of Dom\Text
int(3)
```

Ah... only one of the children in `childNodes` is actually a `Dom\HTMLElement` instance. Also notice the values of `$child->nodeType`: these correspond to some built-in `XML` constants, which we'll look at in a moment. The first and last child nodes in the list are instances of `Dom\Text`, so what gives? This might make more sense if we tweak the input HTML a little:

```
$validHtml = <<<EOS
...
  <body>
    Before main element
    <main>
    ...
    </main>
    After main element
  </body>
...
EOS;
```

All we've done here is add some text above and below the `<main>` tags (inside the `body` element). Let's iterate over `Dom\HTMLDocument::body` again...
