Table 11-15. *XPath mathematical operators*

Operator	Meaning
`+`	Addition
`-`	Subtraction
`*`	Multiplication
`div`	Division
`mod`	Modulo

Table 11-16. *XPath logical operators*

Operator	Meaning
`and`	Logical AND
`or`	Logical OR

There is also a variety of functions available for use in predicates; for example, `//button[contains(text(), "Submit")]` would match `<button>Submit this form </button>` by using the `contains()` function to test that the `button` element text contents (returned by the `text()` function) contains `"Submit"` as a sub-string. There are quite a few functions in XPath, but the ones most likely to see use in the context of parsing HTML are:

Table 11-17. *Some XPath functions*

`name()`	Fetch qualified name of a node or first node in a set
`text()`	Fetch the text inside an element
`contains(haystack, needle)`	True if string `haystack` contains sub-string `needle`
`starts-with(haystack, needle)` `ends-with(haystack, needle)`	True if `haystack` starts/ends with `needle`
`normalize-space(string)`	Remove leading/trailing space from `string`, reduce all space sequences to a single space
`not(EXPR)`	True if expression `EXPR` evaluates to false
`count()`	Get size of node set
`position()`	Index of current node
`last()`	Matches last node
