EOS;

$dom = Dom\XMLDocument::createFromString($xml);
$xpath = new Dom\XPath($dom);
```

Ok, we're all set. Let's play with positional predicates first and show something important:

```
$results = $xpath->query('/data/projects/project[position()=0]');
print "Found {$results->length} matching node(s)" . PHP_EOL;

$results = $xpath->query('/data/projects/project[position()=1]');
print "Found {$results->length} matching node(s)" . PHP_EOL;
var_dump($results[0]->tagName);
var_dump($results[0]->getAttribute('class'));
```
