Next, we'll find somewhere to put it. We've already seen that Dom\Node offers an ::insertBefore() method, as well as ::appendChild(). Dom\Element provides some extra insertion/removal methods that offer a lot more flexibility and power:

Table 11-24. *PHP Dom\Element manipulation methods*

Element::append(...nodes)	Add one or more nodes after last child of Element
Element::insertAdjacentElement (where, node)	Insert node relative to Element controlled by where
Element::insertAdjacentText(where, text)	Insert a text node relative to Element controlled by where
Element::prepend(...nodes)	Add one or more nodes before first child of Element
Element::remove()	Remove Element from the DOM
Element::replaceChildren(... nodes)	Replace current children of Element with new nodes
Element::replaceWith(...nodes)	Replace Element with nodes

Now let's put our newly created img into our DOM, using insertAdjacentElement(), so we can also look at what exactly the where parameter does. The first parameter of Dom\Element::insertAdjacentElement() is taken from the Dom\AdjacentPosition enum, which has four values, which are the strings that the old DOMElement::insertAdjacentPosition() method accepted:

Table 11-25. *PHP Dom\AdjacentPosition / DOMElement equivalence*

Enum	DOMElement string	Detail
AdjacentPosition::BeforeBegin	"beforebegin"	Insert before target element
AdjacentPosition::AfterBegin	"afterbegin"	Insert as first child of target
AdjacentPosition::BeforeEnd	"beforeend	Insert after last child of target
AdjacentPosition::AfterEnd	"afterend"	Insert after target
