```
Output:
bool(false)...
```

Somewhat counter-intuitively, `FILTER_VALIDATE_BOOL` will return `false` even if the input data is an actual honest-to-goodness boolean `false`, as well as when the data is clearly not a boolean at all. Thankfully there is a mitigation for this madness; the flag `FILTER_NULL_ON_FAILURE` will ensure that genuinely non-booleans return `null` instead of `false`:

```
var_dump(filter_var(
    'unsigned 2003 Toyota Yaris',
    FILTER_VALIDATE_BOOL,
    FILTER_NULL_ON_FAILURE
));
```

```
Output:
NULL
```

There are other gotchas in the validation behavior of `filter_var*()`, and we could spend another ten pages going through them all. Most notable is probably `FILTER_VALIDATE_URL`, which implements RFC 2396 to check if a string is a valid URL. That's very nice, but the RFC was obsoleted by 3986. `FILTER_VALIDATE_URL` will return `false` for perfectly valid URLs if they happen to contain non-Latin Unicode characters, which for today's internet is frankly ridiculous.

FILTER_SANITIZE_*

Let's turn our attention to sanitizing. The full list of `FILTER_SANITIZE_*` constants in PHP >= 8.1 is:
