```
    {
    }
}
```

As the output of `phpcs` stated, `phpcbf` will not fix all errors, just the ones concerning layout and spacing. Changing the names of classes and methods will impact any other code relying on them; changing them automatically would be potentially unsafe. If we run `docker-phpcs` again on the file, we can see the remaining issues that need to be addressed:

```
$ dphpcs --standard=PSR12 phpcs_broken.php

FILE: /usr/src/myapp/phpcs_broken.php
----------------------------------------------------------------------
FOUND 4 ERRORS AND 1 WARNING AFFECTING 3 LINES
----------------------------------------------------------------------
 1 | WARNING | A file should declare new symbols (classes, functions,
   |         | constants, etc.) and cause no other side effects, or it
   |         | should execute logic with side effects, but should not do
   |         | both. The first symbol is defined on line 5 and the first
   |         | side effect is on line 3.
 5 | ERROR   | Each class must be in a namespace of at least one level (a
   |         | top-level vendor name)
 5 | ERROR   | Class name "badClassName" is not in PascalCase format
 7 | ERROR   | Method name "badClassName::BadMethodName" is not in camel
   |         | caps format
 7 | ERROR   | Visibility must be declared on method "BadMethodName"
----------------------------------------------------------------------
```

Again, I encourage you to read the PSR-1 and PSR-12 standards in full and make good use of tools like `phpcs`. It's quite common for large PHP projects in professional environments to automatically check standards on changes and prevent any violations from making their way into production code (and usually sending team members pithy emails in the process).
