Overview

The goal of this chapter is to help you design, set up, and improve your database layer so that it can adapt to the changing needs of "myapp." We are going to learn how to make strong Eloquent models that handle one-to-many and many-to-many relationships, so you can easily get your data and manage it. We will work on creating and executing migration files using Laravel Artisan on your Linux setup, making sure that your database schema evolves alongside your application. We will also learn about data seeding techniques to generate consistent, realistic test datasets for thorough development and quality assurance.

The chapter will also teach you some advanced ways to optimize your queries, like using eager loading to cut down on redundant database calls and boost performance. As you go through this, we will be building on practical examples and verified tools like Laravel Debugbar. This'll help you take a cohesive and scalable approach to managing your application's data layer.
