Recipe 1: Deploying Real-time In-app Alerts

In "myapp," you figured out that sending out alerts in real-time is key to keeping users up-to-date with what's going on. In a recent team meeting, you found that users were missing important updates, like new messages, system warnings, or promotional notifications. It wasn't ideal to rely on external tools. You wanted to use Laravel's built-in features to create a seamless and efficient alert system within your application. Then, we will use Laravel's Notification system with database channels to set up in-app alerts. This approach lets you store notifications in the database and show them right in the app. We'll define and send notifications, store them in the database, and finally retrieve and display these alerts on the user interface.

Enabling Database Notifications in App

The Laravel's Notification system is built to handle multiple channels, including email, SMS, and the database. For in-app alerts, we will use the database channel. To do this, first open your **app/Models/User.php** file and confirm that the User model uses the **Notifiable** trait. This enables the user to receive notifications.
