Recipe 3: Integrating Real-time Push Notifications

For now, we've got in-app alerts, email, and SMS notifications to keep your users in the loop. But users have said they want to see notifications delivered right away, even when they're not actively refreshing the page. So, to deal with this, you decided to use push notifications with Laravel's broadcasting features, using Laravel Echo along with a service like Pusher. This setup will allow events to be pushed in real time to the client's browser.

Configuring Broadcasting

To begin with this, at first, you need to configure your Laravel application to use Pusher for broadcasting. For this, you need to add the following configuration values, replacing the placeholders with your actual Pusher credentials in your **.env** file:

BROADCAST_DRIVER=pusher

PUSHER_APP_ID=your-pusher-app-id
