Overview

In this chapter, you are going to explore the job queues and background processes to enhance the performance and reliability of "myapp." You will begin by learning to configure queue drivers so that heavy tasks—such as sending bulk emails or processing large data sets—are offloaded from the main request cycle. You are going to create custom job classes that encapsulate complex business logic, enabling asynchronous processing and non-blocking execution. Furthermore, you will implement robust retry strategies to manage transient errors and log job failures for easier troubleshooting.

In addition to handling individual jobs, you will explore automating recurring tasks using Laravel Scheduler, ensuring that routine maintenance operations run automatically without manual intervention. Throughout this chapter, you practice live through dispatching, monitoring, and processing background tasks using Linux commands and Laravel's built-in tools along with the essential techniques to maintain a highly responsive application even under heavy load.
