Recipe 1: Configuring Queue Drivers

Let us say that we observed some heavy tasks—such as sending large batches of emails, processing image uploads, or generating extensive reports—were directly executed within HTTP requests. This slowed down the user experience but and also impacted overall application responsiveness. Now, to overcome these challenges, we can try to offload such tasks to background processes using Laravel's job queues. Queue drivers allow you to dispatch tasks asynchronously, so they're executed separately from the main request-response cycle. This decoupling of tasks results in a faster, more responsive application and a smoother user experience. So now, you will learn what queue drivers are and how to set them up using Laravel's built-in functionality along with Linux commands, ensuring that heavy tasks are efficiently managed in the background.

Configuring Queue Driver

Queue drivers in Laravel enable you to offload and process time-consuming tasks asynchronously. Instead of executing these tasks during a user request—leading to slow responses—tasks are pushed onto a queue and processed later by a dedicated worker. This is extremely useful for tasks like sending emails, processing
