Recipe 3: Managing Job Failures

Now, let's say you run into some annoying issues where jobs sent for background processing sometimes fail without any obvious fix. For example, during an update to generate reports asynchronously, some jobs never finished because of temporary network errors or short-lived database connectivity issues. It's possible that the reason for the issue is that there's no retry strategy in place, which has led to some operations being incomplete. There's also been a lack of proper error logging, which has made it hard to understand what the problems are. We could try to solve this by using Laravel's built-in retry strategies and failure logging to manage job failures. Today, we will learn how to capture failed jobs, set retry limits for transient errors, and make sure that job failures are properly logged and managed so that your background tasks run reliably.

Configuring Retry Strategy in Job Class

The Laravel allows you to define how many times a job should be attempted before being marked as failed. So, we simply access the custom job class created earlier) and set properties to define retry behavior. In the job class, we add properties for retry attempts and timeout as shown below:
