Recipe 1: Configuring Local Media Storage

In your app you reached a point where handling media files securely on your Linux server became critical for both security and efficiency. Your application deals with sensitive user-uploaded images and documents, which require a protected file storage solution that isolates media files from the public directory and restricts unauthorized access. Now that you recognized the need for a robust system to configure storage paths, control file access permissions, and ensure that your media handling routines operate within a secure environment. So here, you will work towards to configure local storage for media files exclusively on your Linux server, detail the necessary configuration steps in Laravel's settings, and apply Linux commands to secure the storage directories. This teaches you to set up designated storage paths, have the correct folder permissions, and ultimately provide secure access to media assets within our "myapp."

Configuring Storage Paths

The Laravel uses a unified API for file storage that supports local disks, cloud-based disks, and more through the Filesystem abstraction. In our case, we will focus on local storage. The
