```
Route::get('/media/download-chunked/{filename}',
[App\Http\Controllers\MediaController::class,
'downloadFileChunked'])->name('media.download.chunked');
```

This method is useful for serving files that are particularly large, ensuring that the PHP process does not overload its memory limit by processing the file in manageable chunks.

Caching Headers and Content Delivery

To support high traffic, we have to be cautious about caching headers being correctly configured. The above examples include **Cache-Control** headers to allow client and intermediary caches (such as CDNs, if introduced) to store files temporarily, reducing load on the server.

With all these detailed steps, you successfully enabled efficient file streaming and downloads in “myapp” by utilizing Laravel’s built-in response methods and secure file storage configurations.
