Lets say that your application needs to compile and send a summary report every Monday at 8 AM. You have implemented an Artisan command called In the Scheduler configuration, you add:

```
$schedule->command('reports:generate')->weeklyOn(1, '8:00');
```

Test the command manually by running:

```
php artisan reports:generate
```

We need to make sure that the summary report is generated and stored/sent as expected. On Monday at 8:00, the Scheduler sees that the **reports:generate** command is due. With the cron job running every minute, Laravel Scheduler triggers the report generation automatically. And post-execution, you can verify the process by checking the generated reports in your designated storage or by reviewing email logs if the report is emailed.
