Summary

Throughout this chapter, you worked around the automation of routine operations in your app by integrating Laravel Scheduler with Linux cron. You configured the Scheduler within the **Kernel.php** file and defined recurring tasks, such as clearing logs and generating summary reports, ensuring these maintenance processes were executed automatically without manual intervention. You created custom Artisan commands, like the one for generating analytical reports, that aggregated key metrics and stored the resulting data for further analysis. Additionally, you linked Laravel's scheduling with Linux cron by setting up a single cron entry, which triggered **php artisan schedule:run** every minute.

In combination with monitoring tools like Laravel Telescope, Debugbar, and standard Linux utilities in this entire book, your approach ensured that maintenance operations did not overwhelm the system and that performance remained optimal, effectively preparing your app for scalability and high-traffic usage.
