Recipe 2: Configuring Linux File Permissions and Directory Structure

Now that you've got PHP, Composer, and Laravel 11 set up on your Linux machine, like you did in the last recipe, it's time to move on. So, picture this. You've got this basic system set up for Laravel, and it's starting to get data and user interactions. In our busy office, we will get to work on a project, tweaking its structure and security by getting hands-on with the Linux file system. We will need to be able to confidently navigate the Laravel directory structure and learn essential Linux commands, like listing directories, managing ownership, and modifying file permissions. And when you get the hang of these concepts, we will not only be super-skilled in the practical stuff, but we will also be able to keep your Laravel project running smoothly and reliably.

Revisiting Laravel Project Structure

Before diving into permissions, let’s refresh our understanding of the directory structure we created in the first recipe. To do this, first navigate to your project folder, "myapp":
