group) and the web server can modify files here, which is necessary for writing logs, caching data, or uploading files. It also blocks unauthorized modifications from other users on the system.

And, to ensure that these changes have been applied, you try to list the directories' details once more:

---

ls -l storage

ls -l bootstrap/cache

You should see permissions resembling **drwxrwxr-x** for these directories. This output confirms that your adjustments are in place, and both you and the web server can manage the files needed for optimal Laravel performance.

Laravel's Access to File System

It's important to be be well versed with how Laravel leverages these directories in our project. The **storage** directory is not merely a random folder; it's your central hub for dynamic content. It stores application logs in caches compiled views and
