Recipe 2: Implementing RBAC

Since you are expanding your app to include sensitive areas that require controlled access based on user roles, it's important to keep security in mind. So, during a strategy session with your team, you decide that RBAC is vital to make sure that only authorized users can access certain endpoints. In our app, we're going to use roles like "admin", "editor", and "user" to control what each account can do. Today, we are going to use RBAC with Laravel middleware. We will learn how to set up middleware to check user roles, design permission hierarchies, and protect endpoints from unauthorized access. This'll help your app stay secure and follow business rules.

Creating Custom Middleware

First, we begin by creating a custom middleware that will verify a user's role by running:

---

php artisan make:middleware RoleMiddleware
