SUMMARY

- PHP string is a sequence of characters i.e., used to store and manipulate text.
- PHP supports only 256-character set and so that it does not offer native Unicode support.
- Singly quoted strings are treated almost literally, whereas doubly quoted strings replace variables with their values as well as specially interpreting certain character sequences.
- Nowdocs are to single-quoted strings what heredocs are to double-quoted strings. A nowdoc is specified similarly to a heredoc, but no parsing is done inside a nowdoc.
- Parsing is used in all high-level programming languages. Languages like C++ and Java are parsed by their respective compilers before being transformed into executable machine code.
- When a string is specified in double quotes or with heredoc, variables are parsed within it.
- String conversion is automatically done in the scope of an expression where a string is needed.
- The string in PHP is implemented as an array of bytes and an integer indicating the length of the buffer.
- An integer or float is converted to a string representing the number textually (including the exponent part for floats).
